## 1. Acknowledgment

Our sincere thanks to the following, without whose help this project would not have been a success.

- Dr A.A.J. Rajaratne, Head, Department of Physiology, for granting us permission to obtain equipment and conduct the project.
- Prof M. Udupihilla and members of the staff of the Department of Physiology for giving us the basic knowledge on conducting the project.
- Dr Mrs. A. S. Ariyasinghe, Lecturer in charge of our group, without whose support and guidance the project would not have been a success.
- The Time Keeper, Bus Drivers, Conductors, Shop Owners and General Public of Panideniya.
- The Time Keeper, Bus Drivers and conductors of Gampola private bus stand.
- The Bus Drivers and Conductors of Bogambara bus park.
- The Officer in Charge and Staff of the Head Office of Mahanuwara Bus Company and the Bus Drivers of Goods Shed bus stand.
- The Staff of the Kandy branch of the Housing Authority.
- The Officer in Charge and other officers of the Kandy Police Station
- Non Academic Staff, Security officers and contract workers of the Faculty of Medicine who took part as subjects in our project.
- The Technical Staff of the Department of Physiology.
- Mr. Asanka Pilapitiya for providing us transport from Gampola to Kandy.
- Batch Mates who helped us in numerous ways.

## Thank you everybody.

## 2. Abstract

## A Comparative Study of Blood Pressure of Sri Lankan Bus Drivers

## Introduction

Initial observations showed that Sri Lankan bus drivers worked in quite a stressful environment. Therefore it was hypothesized that they have a higher average mean arterial pressure compared to the general public. The aims and objectives of this study was to determine whether the average Mean Arterial Pressure of bus drivers showed a significant change compared to a control group and to determine whether bus drivers were exposed to risk factors of hypertension more than the control group.

## Materials and Methods

Blood Pressure and Heart rate were measured in 117 bus drivers and 123 age and BMI matched controls chosen randomly from the general public. Data regarding age, height, weight, alcohol consumption, smoking habits, pressure medication, cardiovascular diseases in subject and family, diabetes in subject and number of working hours per day and days per week were obtained using a data collection sheet.

Age ( 25 to 55 years) and BMI ( 17 to $35 \mathrm{~kg} / \mathrm{m} 2$ ) were controlled. Bus conductors and other professional drivers were excluded.

## Results and Analysis

Mean arterial pressures were compared using the unpaired students $t$-test. Exposure to risk factors was compared using pie charts and bar graphs.

There was a significant difference ( $\mathrm{P}<0.05$ and $\mathrm{t}=2.177$ ) in mean arterial pressure between bus drivers and the controls. Also there were significant changes in diastolic blood pressure ( $\mathrm{t}=2.731$ and $\mathrm{P}<0.05$ ) and heart rate ( $\mathrm{t}=2.433$ and $\mathrm{P}<0.05$ )

The percentage of smokers was higher in bus drivers (51\%) compared to the controls (36\%).

Bus drivers worked on average 281.4 hours per month compared to 260.9 hours per month by the controls, which showed a significance difference ( $\mathrm{P}<0.05$ ).

Other risk factors did not show great changes.

## Conclusions

The conclusions in this study were that average mean arterial pressure of bus drivers was significantly higher compared to the control group and that this may have been due to the higher percentage of smokers and the higher number of working hours per month in bus drivers compared to the controls.

## 3. Introduction

Driving a vehicle in Sri Lanka is a very difficult and strenuous task. Narrow roads, potholes and reckless driving together with undisciplined pedestrians make driving safely in Sri Lanka almost impossible.

These conditions apply to bus drivers as well who unlike in other countries race rickety old buses without automatic gears or power steering along typical Sri Lankan roads, most of the time competing with fellow drivers to get the most number of passengers in the least amount of time during a particular turn.

There is a lot of breath taking overtaking, hard breaking and also waiting for long periods of time stuck in city traffic in the hot tropical sun, breathing dust and vehicle smoke, accompanied by continuous vibrations from start to finish. These initial observations led us to believe that Sri Lankan bus drivers may have different blood pressure values compared to people of other occupations.

The term blood pressure usually means arterial blood pressure and is the force that drives blood through the body tissues. Measurement of blood pressure is done to test the normal functioning of the cardiovascular system. The pressure in the major arteries rise to a peak value called systolic pressure during contraction of the heart and then falls to a minimum figure called diastolic pressure during relaxation of the heart. Traditionally the arterial blood pressure is given in millimeters of mercury ( mmHg ) as systolic pressure over diastolic pressure with $120 / 80 \mathrm{mmHg}$ being cited as the normal value in many references. But variations do not necessarily mean an abnormality (Dale, 1997).

There are two main physiological factors that affect blood pressure i.e. cardiac output and peripheral resistance. Both of these factors have a direct relationship with blood pressure. A change in cardiac output will normally affect systolic pressure and a change in peripheral resistance will normally affect diastolic pressure.

There are also two physical factors that affect blood pressure. They are blood volume and arterial elasticity. Arteries have an elastic nature and tend to expand with increased blood flow. But with progressive atherosclerosis, there is a tendency for the elasticity to reduce, thus increasing the blood pressure (Berne, 1992).

Hypertension occurs when blood pressure is constantly higher than normal in an individual (for that persons age group.). A blood pressure value over $140 / 90 \mathrm{mmHg}$ is taken as hypertension (Dale, 1997).

Hypertension is a form of cardiovascular disease (CVD) and out of a recorded 925079 CVD deaths, hypertension accounted for 35,830 in a study conducted in the United States (Dale, 1997).

### 3.1 Risk factors of hypertension

## 1. Age

There is a tendency for blood pressure to rise with the age, becoming quite marked in the elderly (McGeown, 2002). This means that when defining normal blood pressure, the age of the person should be taken into consideration. The increase with age may be explained by the decreased compliance and elasticity of the arteries with ageing (Case, 1994). A study on bus and truck drivers has shown that the difference of blood pressure increased with age (Hartvig, 1983)

## 2. BMI, Diet and Obesity

The Body Mass Index (BMI) is used to obtain a relationship of an individuals weight and height and to determine whether a individual is at a healthy weight. It is thought to be an accurate indicator of body fat content. To obtain the BMI value weight of an individual (in kilograms) is divided by the height (in meters) squared. The BMI values obtained from people can be interpreted in the following manner according to the WHO criteria.

$$
\begin{array}{ll}
\text { BMI<18.5 } & \text { - Underweight } \\
\text { BMI 18.5-24.9 } & \text { Normal weight } \\
\text { BMI 25.0-29.9 } & \text { Overweight } \\
\text { BMI>30.0 } & \text { Obese }
\end{array}
$$

In overweight and obese people the serum lipid content is high and in obese people, the risk of atherosclerosis and hypertension is high (Dupuy, 1995). A study has shown that there is a tendency for hypertension to increase with degree of obesity (Ueda, 1992)

One of the main reasons for obesity is bad dietary habits. Consuming food rich in fat and carbohydrate may lead to obesity. Consumption of salt may increase blood pressure. The degree to which hypertension can be ameliorated or prevented will obviously vary with the salt sensitivity of the individual. (Ganong, 1999)

## 3. Alcohol

Alcohol consumption causes hyperlipidemia by increasing the serum Very Low Density Lipoprotein (VLDL) and cholesterol concentrations. This has been shown to lead to atherosclerosis and hypertension. (Motulsky, 1989).

Studies have shown that consumption of $200 \mathrm{~g}-300 \mathrm{~g}$ of alcohol per day is associated with increases in blood pressure. People who consume an average of two or more drinks per day ( $>30 \mathrm{ml}$ ) have higher mean blood pressure levels and prevalence of hypertension than people who drink small quantities. Also epidemiological studies have shown that chronic alcohol consumption is associated with high blood pressure (Motulsky, 1989).

## 4. Smoking

Nicotine in cigarette smoke has a similar action to sympathetic nerve stimulation of the cardiovascular system and increase the blood pressure. In people with hypertension, nicotine produces a further rise in blood pressure and it has been shown
that in both men and women, smoking is associated with an increase in blood pressure (Ashton, 1982).

Studies have shown that the risk of having carotid atherosclerosis for a person who had smoked for 40 years was approximately 3.5 times that of a non smoker (Whisnant, 1990). Atherosclerosis as we know lead to increased blood pressure values.

## 5. Diabetes

In patients with uncontrolled Diabetes Mellitus, the tissues cannot take up glucose for energy production and thus tend to use fatty acids. This causes an increased serum lipid concentration leading to atherosclerosis. Therefore hypertension may occur in diabetics secondary to atherosclerosis and also renal injury caused by high blood sugar concentrations (Guyton, 1996).

## 6. Stress

Stress can be divided into two categories i.e. psychological stress and physical stress. Psychological stress may develop due to problems in the home, work place ect. A probable but not commonly accepted theory, is that psychological indicators may influence the traditional risk factors (of hypertension) in a harmful way (Hartvig, 1983)

Physical activity such as driving can cause physical stress. Blood Pressure was shown to be higher when driving or loading than when resting or on a day off (Sato,1999). One study showed that professional drivers showed more than twice the overall exposure to stressful work factors compared to referents (Belkic, 1998). Another study showed that there was a positive association between diastolic blood pressure and cumulative working time (Cordeiro, 1993).

During stress there is increased blood levels of cortisol and catecholamines, which increase serum lipid concentration and metabolic activity (Burgess, 1992).

Therefore continuous exposure to stress will increase the risk of atherosclerosis, which together with increased metabolic activity can increase the arterial pressure.

Exercise which can deemed a form of physical stress can on one hand increase blood pressure due to increased metabolic activity. But in the long run it may reduce the risk of atherosclerosis by reducing serum lipid concentrations and thus reduce the prevalence of high blood pressure.

## 7. Race

Studies have been done to see if race has a relationship with blood pressure, using blacks and whites as subjects (Albright, 1992). But the relevance of this to Sri Lanka is not known.

### 3.2 Hypothesis

Our hypothesis is that, the mean arterial pressure of bus drivers is higher than that of the controls.

## 4. Aims and Objectives

The aims and objectives of this study were,

- To determine whether the Mean Arterial Pressure of bus drivers shows a significant difference compared to a control group.
- To determine whether bus drivers are exposed to risk factors of hypertension more than the control group.

## 5. Materials and Methods

## Sampling

To fulfill our aims and objectives, it was decided to obtain Blood Pressure, Heart Rate and other relevant data of bus drivers and an age and BMI-matched control group (in other occupations) comprising of the general public.

## Inclusion Criteria

All subjects chosen were males, aged between 25 and 55 years and had a BMI between 17 and $35 \mathrm{~kg} / \mathrm{m} 2$

## Exclusion Criteria

Subjects outside the above age and BMI ranges, females, bus conductors and other professional drivers (eg. three wheeler drivers, van drivers) and people with visible mental and physical illnesses were excluded.

## Choosing of Bus Drivers

Panideniya town, Gampola privet bus stand, Bogambara bus park, Goods-Shed bus stand were targeted as potential data collection sites for bus drivers.

## Choosing of Controls

The Medical Faculty premises, Panideniya Town, Kandy office of the housing authority and the Kandy Police Station were targeted as potential data collection sites for controls.

## Taking Information regarding Risk Factors

As volunteers came forward at the data collection sites, they were comfortably seated and explained what was to be done. After their consent was taken, they were asked to fill a questionnaire regarding Age, Alcohol Intake, Smoking Habits, Pressure Medication, history of Cardiovascular Disease in the subject and his family, history of Diabetes and number of hours on the job. Drivers were asked the route they worked and the distance driven per day as well as the number of years working as a driver. Controls were asked for their occupation. All information was noted in a data collection sheets, (See Appendix p.22)

## Measuring Heart Rate and Blood Pressure.

At least five minutes were taken to fulfill the above task so as to rest the volunteers as much as possible prior to blood pressure measurement. Next the heart rate was noted by palpating the radial pulse. Blood pressure was measured by the noninvasive manual Auscultatory method using a mercury sphygmomanometer and a stethoscope.

The clothing was removed completely from the right arm and the cuff of the sphygmomanometer was tightly wrapped around the brachium so that its lower border was roughly two to three centimeters above the cubital fossa. It was made sure that the sphygmomanometer, cuff and the observer's eye were at the same level as the heart of the volunteer.

Then the stethoscope was placed on the cubital fossa of the volunteer (where the brachial artery is supposed to be) and the pressure was increased above the systolic pressure. Next the pressure was reduced little by little until rhythmic tapping 'Korotkoff' sounds were first heard and the pressure at this point was noted as systolic pressure. The pressure was then further reduced until the Korotkoff sounds suddenly became faint and disappeared and the pressure at this point was noted as the diastolic pressure.

## Measuring the Height

After measuring the blood pressure, the height of each volunteer was measured using a measuring tape, after the volunteer removed his footwear. It was made sure that the volunteer had his feet together and stood as erect as possible while looking directly forward and had his back to the measuring surface. (E.g.: a wall)

## Measuring the Weight

The weight of the volunteers was measured using a bathroom scale after they removed their footwear and emptied their pockets.

Blood pressure was measured twice in volunteers whose blood pressure was over $140 / 90 \mathrm{mmHg}$ after they rested for another five minutes.

## Statistical analysis

All data collected was computed and analyzed using Microsoft Excel and SPSS and interpreted as required to fulfill our aims and objectives.

## 6. Results

A total of 117 bus drivers and 123 controls from the general public volunteered for the study. All the subjects were males. The results obtained by the analysis of data are shown below. The age range for all the subjects was 25 to 55 years and the BMI range was 17 to $35 \mathrm{~kg} / \mathrm{m}^{2}$

Fig 1: Systolic, diastolic and mean arterial blood pressures in bus drivers and controls.

The above graph shows that the mean systolic and diastolic blood pressures and average mean arterial pressure is higher in the bus drivers than the controls.

Table 1: Mean Arterial Pressures in bus drivers and controls

| SUBJECT | Mean <br> $(\mathrm{mmHg})$ | N | Std. <br> Deviation |
| :--- | ---: | :---: | :---: |
| Drivers | 101.45 | 117 | 12.79 |
| Controls | 97.86 | 123 | 12.74 |
| Total | 99.61 | 240 | 12.87 |

The above table shows that the average mean arterial pressure of bus drivers is higher than that of the controls.

Table 2: Independent Samples t-Test for Mean Arterial Pressure between bus drivers and controls

|  | t-test for Equality of Means |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | T Value | $\begin{array}{\|c\|} \hline \begin{array}{c} \text { Degree } \\ \text { of } \\ \text { Freedom } \end{array} \\ \hline \end{array}$ | $\begin{aligned} & \text { Significance } \\ & \text { (2-tailed) } \end{aligned}$ | Mean Difference | Std. Error Difference | $\begin{gathered} \text { 95\% Co } \\ \text { Interva } \\ \text { Diff } \end{gathered}$ | fidence of the ence |
|  |  |  |  |  |  | Lower | Upper |
| Equal variances assumed | 2.177 | 238 | . 030 | 3.59 | 1.65 | . 34 | 6.84 |

According to the above table, $\mathrm{t}=2.177$ and $\mathrm{P}<0.05$. Therefore there is a significant difference in the mean blood pressures between two groups, at a confidence interval of $95 \%$.

Table 3: Mean Systolic Blood Pressures in bus drivers and controls

| SUBJECT | Mean <br> $(\mathrm{mmHg})$ | N | Std. <br> Deviation |
| :--- | ---: | :---: | :---: |
| Drivers | 126.58 | 117 | 14.69 |
| Controls | 124.81 | 123 | 16.35 |
| Total | 125.67 | 240 | 15.55 |

The above table shows that the mean systolic blood pressure is slightly higher in the drivers than the control group.

Table 4: Independent Samples t-Test for Systolic Blood Pressure in bus drivers and controls

|  | t -test for Equality of Means |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | T | Degree <br> of <br> Freedom | Significance <br> (2-tailed) | Mean <br> Difference | Std. Error <br> Difference | 95\% Confidence <br> Interval of the <br> Difference |  |  |
| Equal <br> variances <br> assumed | .880 | 238 | .380 | 1.77 | 2.01 | -2.19 | 5.73 |  |

According to the above table, $\mathrm{t}=0.880$ and $\mathrm{P}>0.05$. Therefore there is no significant difference in the systolic blood pressures between the two groups.

Table 5: Mean Diastolic Blood Pressures in bus drivers and controls

| SUBJECT | Mean <br> $(\mathrm{mmHg})$ | N | Std. <br> Deviation |
| :--- | ---: | :---: | :---: |
| Drivers | 88.89 | 117 | 13.22 |
| Controls | 84.39 | 123 | 12.30 |
| Total | 86.58 | 240 | 12.93 |

The above table shows that mean diastolic pressure is higher in the drivers than the control group.

Table 6: Independent Samples Test for Diastolic Blood Pressure in bus drivers and controls

|  | t-test for Equality of Means |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | T | Degree <br> of <br> Freedom | Significance <br> (2-tailed) | Mean <br> Difference | Std. Error <br> Difference | 95\% Confidence <br> Interval of the <br> Difference |  |
| Equal <br> variances <br> assumed | 2.731 | 238 | .007 | 4.50 | 1.65 | 1.25 | 7.74 |
|  |  |  |  |  |  | Lower | Upper |

According to the above table, $\mathrm{t}=2.731$ and $\mathrm{P}<0.01$.Therefore ,there is a significant difference in the diastolic blood pressures of the two groups, at a confidence interval of 95\%.

Fig 2: Mean heart rate in bus drivers and controls.

Table 7: Mean Heart Rate in bus drivers and controls.

| SUBJECT | Mean <br> $(\mathrm{mmHg})$ | N | Std. <br> Deviation |
| :--- | ---: | :---: | :---: |
| Drivers | 73.51 | 117 | 8.91 |
| Controls | 70.63 | 123 | 9.40 |
| Total | 72.04 | 240 | 9.26 |

The above table and graph shows that bus drivers have a higher average heart rate than the controls.

Table 8: Independent Samples t-Test for Heart Rate between bus drivers and controls

|  | t -test for Equality of Means |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | T | Degree <br> of <br> Freedom | Significance <br> (2-tailed) | Mean <br> Difference | Std. Error <br> Difference | 95\% Confidence <br> Interval of the <br> Difference |  |
| Equal <br> variances <br> assumed | 2.433 | 238 | .016 | 2.88 | 1.18 | .55 | 5.21 |

According to the above table, $\mathrm{t}=2.433$ and $\mathrm{P}<0.05$.Therefore there is a significant difference in the heart rate between the two groups, at a confidence interval of $95 \%$.

Fig.3: Average number of working hours in bus drivers and controls.
The above graph shows that bus drivers on average work more hours per month than controls

Table 9: Average number of Working Hours in bus drivers and controls

| SUBJECT | Mean | N | Std. <br> Deviation |
| :--- | ---: | :---: | :---: |
| Drivers | 281.41 | 117 | 75.22 |
| Controls | 260.59 | 123 | 73.83 |
| Total | 270.74 | 240 | 75.08 |

The above graph(3) and table(9) show that bus drivers on average work more hours per month than controls

Table 10: Independent Samples t-Test for Working Hours between bus drivers and controls

|  | t-test for Equality of Means |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | T | Degree <br> of <br> Freedom | Significance <br> (2-tailed) | Mean <br> Difference | Std. Error <br> Difference | 95\% Confidence <br> Interval of the <br> Difference |  |
| Equal <br> variances <br> assumed | 2.164 | 238 | .031 | 20.82 | 9.62 | 1.87 | 39.78 |
|  |  |  |  |  | Lower | Upper |  |

According to the above table $\mathrm{t}=2.164$ and $\mathrm{P}<0.05$. Therefore there is a significant difference in the average working hours between the two groups.

A

B

Fig. 4: The percentage of smokers and non-smokers among bus drivers (A) and controls (B).

The above charts show that the percentage of smokers is higher in the bus drivers (51\%) compared to the control group (36\%).

Fig.5: The percentage of alcohol consumption among bus drivers (A) and controls (B).

The above charts show that the percentage consuming alcohol is similar in both bus drivers (53\%) and controls (53\%).

## A <br> B

Fig.6: The obese percentages of drivers (A) and controls (B).
The above charts show that the obese percentage is higher in bus drivers (A) compared to controls (B).

## A <br> B

Fig.7: The overweight percentages of drivers (A) and controls (B).
The above charts show that the overweight percentage is higher in controls (B) compared to bus drivers (A).

Fig. 8: The percentage among drivers and controls, exposed to risk factors such as smoking, alcohol consumption, obesity ,medication, history and family history of cardiovascular disease(CVD) and diabetes.

The above graph shows that the percentages of smokers and obese individuals were higher in drivers than controls. The percentage of subjects with a history of cardiovascular disease and diabetes was slightly higher in the controls. But there was no difference in the percentage of subjects consuming alcohol among bus drivers and controls.

## 7. Discussion

Proving our hypothesis correct, the mean arterial pressure of the bus drivers was found to be statistically higher than the control group. Average heart rate and average diastolic pressure were also statistically higher in bus drivers compared to the controls while the average systolic pressure was not significantly different. Therefore the increase in the mean arterial pressure could be due to the increased diastolic pressure.

When considering the risk factors, the percentage of smokers was considerably higher in the bus drivers compared to the controls. Also the number of working hours per month was statistically higher in the drivers. Therefore we can hypothesize that smoking and work stress could have caused the increased mean arterial pressure values in the bus drivers. This hypothesis is supported by several studies. (Whisnant, 1990 and Cordeiro, 1993)

The percentages having cardiovascular diseases and diabetes and a family history of these diseases and the percentage taking pressure medication were all higher in the control group compared to the drivers. The percentage of obese individuals was higher in the drivers. But the percentage differences in the above factors were small and also the overall percentage with positive results, as a whole was small. So these factors do not seem to have an effect on the mean arterial pressures.

Though a large percentage consumed alcohol in both groups, there was no difference between the two groups. Therefore the effect of alcohol consumption on the difference in the mean arterial pressures between the two groups seems to be minimal.

Zero percent prevalence of diabetes and also lower cardiovascular disease prevalence among the drivers can be due to actually, lack of awareness about these diseases. It is our view that basic health education programmes about these diseases and also about the negative effects of smoking ect may help them. A reduction in working hours per month may also help to reduce the occupation related stress of bus drivers.

## 8. Conclusions

From the results obtained we concluded that the mean arterial pressure of bus drivers is statistically higher compared to the control group and this may be due to the higher percentage of smokers among bus drivers and the higher number of working hours per month in bus drivers.
